MEAN AND POINTWISE ERGODIC THEOREMS FOR COSINE OPERATOR FUNCTIONS

SEN-YEN SHAW

1. Introduction. The purpose of this paper is to present a mean ergodic theorem and two pointwise ergodic theorems for a strongly continuous cosine operator function.

Let X be a Banach space and $B(X)$ be the Banach algebra of all bounded linear operators on X . A one-parameter family $\{C(t) ; t \geq 0\}$ in $B(X)$ is called a strongly continuous cosine function if it satisfies the three conditions:

- (1) $C(t+s) + C(t-s) = 2C(t)C(s)$ for all $t \geq s \geq 0$;
- (2) $C(0) = I$ (the identity operator) ;
- (3) $C(t)$ is strongly continuous in t on $[0, \infty)$.

The associated sine function $S(\cdot)$ is defined by $S(t)x = \int_0^t C(s)x ds$ ($x \in X$).

There exist constants $w > 0$ and $M_w > 0$ such that $\|C(t)\| \leq M_w e^{wt}$ for all $t \geq 0$. We shall denote by w_0 the infimum of the set of all such w and call it the type of $C(\cdot)$. Let A be the infinitesimal generator of $C(\cdot)$, defined as $Ax := \lim_{t \rightarrow 0^+} 2t^{-2}(C(t) - I)x$ in its natural domain $D(A)$. Then

A is a densely defined closed operator, the resolvent set $\rho(A)$ contains all λ^2 with $\lambda > w_0$, and for each such λ

$$\lambda(\lambda^2 I - A)^{-1} = \int_0^\infty e^{-\lambda t} C(t) dt.$$

We shall use $L(\lambda)$ to denote this operator. For these and other fundamental properties of $C(\cdot)$ the reader is referred to [3] and [11].

The operators $t^{-1}S(t)$, $t > 0$, and $\lambda L(\lambda)$, $\lambda > 0$, are the Cesaro averages and the Abel averages of $C(\cdot)$, respectively. In section 2 we shall relate the convergence of $\lim_{t \rightarrow \infty} t^{-1}S(t)x$, $\lim_{\lambda \rightarrow 0} \lambda L(\lambda)x$, and $\lim_{n \rightarrow \infty} n^{-1} \sum_{i=0}^{n-1} C(it)x$.

In section 3, X is assumed to be a Lebesgue space $L_p(S, \Sigma, \mu; Y)$, $1 \leq p < \infty$, with Y a reflexive space. Under suitable conditions the almost everywhere convergence of $t^{-1}S(t)f$ for $f \in L_p \cap L_\infty$ and of $\lambda L(\lambda)f$ for f in L_p will be justified.

2. Mean ergodic theorems. Suppose $C(\cdot)$ is a strongly continuous cosine function such that $\|C(t)\| \leq M$ for all $t \geq 0$. Then $C(\cdot)$ has type $w_0 = 0$. We denote by P_c [resp. P_a] the operator defined by

$$P_c x := \lim_{t \rightarrow \infty} t^{-1} S(t)x \text{ [resp. } P_a := \lim_{\lambda \rightarrow 0} \lambda L(\lambda)x],$$

with domain consisting of all those x for which the limit exists. Also we define for each $t > 0$ the operator P_t by

$$P_t x := \lim_{n \rightarrow \infty} n^{-1} \sum_{i=0}^{n-1} C(it)x.$$

The following theorem is proved in [10]; it characterizes the range $R(P_c)$, the null space $N(P_c)$, and the domain $D(P_c)$ of P_c , and also those of P_t .

Theorem A. Under the hypothesis: $\|C(t)\| \leq M$ for all $t \geq 0$, one has:

- (i) $P_c = P_a$ and is a bounded linear projection with $R(P_c) = N(A) = \bigcap_{s>0} N(C(s)-I)$, $N(P_c) = \overline{R(A)} = \overline{\bigcup_{s>0} R(C(s)-I)}$, and $D(P_c) = \bigcap_{s>0} N(C(s)-I) \oplus \overline{\bigcup_{s>0} R(C(s)-I)}$
 $= \{x \in X; \exists |t_n| \rightarrow \infty \ni \text{w-}\lim_{n \rightarrow \infty} t_n^{-1} S(t_n)x \text{ exists}\}.$
- (ii) For each $t > 0$, P_t is a bounded linear projection with $R(P_t) = N(C(t)-I)$, $N(P_t) = \overline{R(C(t)-I)}$, and $D(P_t) = N(C(t)-I) \oplus \overline{R(C(t)-I)}$
 $= \{x \in X; \exists \{n_k\} \rightarrow \infty \ni \text{w-}\lim_{k \rightarrow \infty} n_k^{-1} \sum_{i=0}^{n_k-1} C(it)x \text{ exists}\}.$

We shall use the above theorem to prove the following theorem, which gives a sufficient condition for P_t to coincide with P_c . It is known that the same assertion holds for semigroups (cf. Sato [8]).

Theorem 1. Let $C(\cdot)$ be a strongly continuous cosine function of uniformly bounded operators. Suppose there exists a $\delta > 0$ such that $C(t)+I$ is invertible (particularly, $\|C(t)-I\| < 2$) for all $t \in (0, \delta)$. Then $P_t = P_c$ for all $t \in (0, 2\delta)$.

Proof. Since by Theorem A one has that $R(P_c) \subset R(P_t)$ and $N(P_t) \subset N(P_c)$, it remains for us to show $R(P_t) \subset D(P_c)$ and $N(P_c) \subset N(P_t)$ for all t in $(0, 2\delta)$.

Using (1) we can easily show by induction that each $C(it) - I$ is a polynomial of $C(t)$ and is divisible by $C(t) - I$. Also we can write

$$\begin{aligned} & \left(\left(n - \frac{1}{2} \right) t \right)^{-1} S \left(\left(n - \frac{1}{2} \right) t \right) \\ &= \left(\left(n - \frac{1}{2} \right) t \right)^{-1} \left\{ \int_0^{\frac{1}{2}t} + \sum_{i=1}^{n-1} \left[\int_{(i-\frac{1}{2})t}^{it} + \int_{it}^{(i+\frac{1}{2})t} \right] \right\} C(s) ds \\ &= \left(\left(n - \frac{1}{2} \right) t \right)^{-1} \left\{ S \left(\frac{1}{2} t \right) + \sum_{i=0}^{n-1} \int_0^{\frac{1}{2}t} [C(it-s) + C(it+s)] ds \right\} \\ &= \left(\left(n - \frac{1}{2} \right) t \right)^{-1} \left\{ S \left(\frac{1}{2} t \right) + \sum_{i=1}^{n-1} \int_0^{\frac{1}{2}t} 2C(s) C(it) ds \right\} \\ &= \frac{2n}{2n-1} (t/2)^{-1} S(t/2) \left[n^{-1} \sum_{i=0}^{n-1} C(it) \right]. \end{aligned}$$

Hence, if $x \in R(P_t) = N(C(t) - I)$, then $x \in N(C(it) - I)$ so that

$$\left(\left(n - \frac{1}{2} \right) t \right)^{-1} S \left(\left(n - \frac{1}{2} \right) t \right) x = \frac{2n}{2n-1} (t/2)^{-1} S(t/2) x,$$

which converges to $(t/2)^{-1} S(t/2) x$ as $n \rightarrow \infty$. So, Theorem A(i) implies that x belongs to $D(P_c)$.

Next, let E be the set of all $s > 0$ such that $R(C(s) - I)$ is contained in $\overline{R(C(t) - I)}$. Then to show $N(P_c) \subset N(P_t)$ is equivalent to showing that $E = (0, \infty)$. We first prove $t/2 \in E$. If $x \in R(C(t/2) - I)$, then we have

$$\begin{aligned} & \frac{1}{2} \left[I + C \left(\frac{t}{2} \right) \right] \left[\frac{1}{n} \sum_{i=0}^{n-1} C(it) \right] x \\ &= \frac{1}{2n} \left\{ \sum_{i=0}^{n-1} C(it) + C \left(\frac{t}{2} \right) + \frac{1}{2} \sum_{i=1}^{n-1} \left[C \left((2i+1) \frac{t}{2} \right) + C \left((2i-1) \frac{t}{2} \right) \right] \right\} x \\ &= \frac{1}{2n} \sum_{j=0}^{2n-1} C \left(j \frac{t}{2} \right) x + \frac{1}{2n} \left[C \left(\frac{t}{2} \right) - C \left((2n-1) \frac{t}{2} \right) \right] x, \end{aligned}$$

which converges to $P_{t/2} x = 0$ as $n \rightarrow \infty$. Since $I + C(t/2)$ is invertible, we must have that $P_t x = \lim_{n \rightarrow \infty} n^{-1} \sum_{i=0}^{n-1} C(it) x = 0$, i. e. $x \in \overline{R(C(t) - I)}$. Repeating the same process and noting that $C(ms) - I$ is divisible by $C(s) - I$, we see that E contains all numbers of the form $(m/2^n)t$, $m, n = 1, 2, \dots$, which form a dense subset of $(0, \infty)$. Then the strong continuity of $C(\cdot)$ shows that the whole set $(0, \infty)$ is contained in E . Hence the theorem is proved.

3. Pointwise ergodic theorems. Throughout this section, (S, Σ, μ) is

a σ -finite measure space, $(Y, \|\cdot\|)$ is a reflexive Banach space, and $C(\cdot)$ is a strongly continuous cosine function of linear operators on $L_1 = L_1(S, \Sigma, \mu; Y)$. In addition, we assume that $\|C(t)\|_1 \leq 1$ for all $t \geq 0$, and that for some constant $K \geq 1$ $\sup_{t \geq 0} \|C(t)f\|_\infty \leq K \|f\|_\infty$ for all $f \in L_1 \cap L_\infty$.

It is known that each $C(t)$ can be extended so that it is defined on each $L_p = L_p(S, \Sigma, \mu; Y)$, $1 \leq p < \infty$ (see [1]), and the extended operator $C(t)$ has norm $\|C(t)\|_p \leq K$, by the Riesz convexity theorem (see [2, VI. 10. 11]). Thus for each $1 \leq p < \infty$ $C(\cdot)$ is a cosine function of operators on L_p . Moreover, it is strongly continuous on $(0, \infty)$. To see this let $f \in L_1 \cap L_p$ so that the function $C(\cdot)f$ is continuous in L_1 and hence $(C(t)f)(s)$ is $[t, s]$ -measurable on $(0, \infty) \times S$ (cf. [2, III. 11. 16-(a)]). It follows from part (b) of the same lemma that $C(\cdot)f$ as a L_p -valued function is Lebesgue measurable on $(0, \infty)$. Since $L_1 \cap L_p$, $1 \leq p < \infty$, is dense in L_p , $C(\cdot)$ is strongly measurable on $(0, \infty)$ when regarded as operators on L_p . It follows that $C(\cdot)$ is strongly continuous on $(0, \infty)$ ([3], [7]) and hence is also right continuous at 0, by (1).

By Theorem III.11.17 of [2] there is for each $f \in L_p$ a Y -valued function $g(t, s)$, defined on $(0, \infty) \times S$ and strongly measurable with respect to the product of Lebesgue measure and μ , such that for each fixed $t > 0$ $g(t, s)$ as a function of s belongs to the equivalence class of $C(t)f \in L_p$. We shall denote this function $g(t, s)$ by the notation $(C(t)f)(s)$. The same theorem also shows the existence of a μ -null set $N(f)$, dependent on f but independent of t , such that for every s not in $N(f)$ $(C(\cdot)f)(s)$ is Bochner integrable on every finite interval $[0, t]$ with respect to Lebesgue measure, and the function $s \rightarrow (S(t)f)(s) := \int_0^t (C(u)f)(s) du$ belongs to the equivalence class of $S(t)f \in L_p$. Similarly, there exists a μ -null set $N'(f)$, dependent on f but independent of t , such that for every s not in $N'(f)$ the function $t \rightarrow e^{-\lambda t}(C(t)f)(s)$ is Bochner integrable on $(0, \infty)$, and the function $s \rightarrow (L(\lambda)f)(s) := \int_0^\infty e^{-\lambda t}(C(t)f)(s) dt$ belongs to the equivalence class of $L(\lambda)f \in L_p$.

The pointwise ergodic theorems are concerned with μ -almost everywhere convergence of $t^{-1}(S(t)f)(s)$ and $\lambda(L(\lambda)f)(s)$ as $t \rightarrow \infty$ and $\lambda \rightarrow 0^+$, or as $t \rightarrow 0^+$ and $\lambda \rightarrow \infty$. They are stated as follows.

Theorem 2. *Let Y be a reflexive Banach space, (S, Σ, μ) a σ -finite measure space, and let $C(\cdot)$ be a strongly continuous cosine function of*

linear contractions on $L_1(S, \Sigma, \mu; Y)$ such that, for some constant $K \geq 1$, $\sup_{t \geq 0} \|C(t)f\|_\infty \leq K \|f\|_\infty$ for all $f \in L_1 \cap L_\infty$. Then the following statements hold for all $1 \leq p < \infty$:

- (i) For every $f \in L_p$ the Abel ergodic limit $f_1(s) := \lim_{\lambda \rightarrow 0^+} \lambda(L(\lambda)f)(s)$ exists almost everywhere on S .
- (ii) For every $f \in L_p \cap L_\infty$ the Cesàro ergodic limit $\lim_{t \rightarrow \infty} t^{-1}(S(t)f)(s)$ exists and equals $f_1(s)$ for almost all s in S .

Theorem 3. Let Y and $C(\cdot)$ be as assumed in Theorem 2. Then the following statements hold for all $1 \leq p < \infty$:

- (i) For every $f \in L_p$ the Abel ergodic limit $f_2(s) := \lim_{\lambda \rightarrow \infty} \lambda(L(\lambda)f)(s)$ exists almost everywhere on S .
- (ii) For every $f \in L_p \cap L_\infty$ the local Cesàro ergodic limit $\lim_{t \rightarrow 0^+} t^{-1}(S(t)f)(s)$ exists and equals $f_2(s)$ for almost all s in S .

Since $\|C(t)\|_1 \leq 1$ for all $t > 0$, $C(\cdot)$ has type $w_0 = 0$ so that the resolvent $R_\lambda = (\lambda I - A)^{-1} = \lambda^{-\frac{1}{2}} L(\lambda^{\frac{1}{2}})$ exists for all $\lambda > 0$. Moreover, we have $\|\lambda R_\lambda\|_1 \leq 1$ and for all $f \in L_1 \cap L_\infty$ and almost all $s \in S$

$$\begin{aligned} |\lambda(R_\lambda f)(s)| &= |\lambda^{\frac{1}{2}} \int_0^\infty e^{-\lambda^{\frac{1}{2}} t} (C(t)f)(s) dt| \leq \lambda^{\frac{1}{2}} \int_0^\infty e^{-\lambda^{\frac{1}{2}} t} |(C(t)f)(s)| dt \\ &\leq \lambda^{\frac{1}{2}} \int_0^\infty e^{-\lambda^{\frac{1}{2}} t} \|C(t)f\|_\infty dt \leq K \|f\|_\infty, \end{aligned}$$

i. e. $\|\lambda R_\lambda f\|_\infty \leq K \|f\|_\infty$. Hence $\{R_\lambda; 0 < \lambda < \infty\}$ satisfies the conditions in the following pointwise ergodic theorem of Sato [9] for pseudo-resolvents, and consequently the Abel averages $\lambda(L(\lambda)f)(s)$ converge almost everywhere for all $f \in L_p$, as either $\lambda \rightarrow 0^+$ or $\lambda \rightarrow \infty$.

Theorem B. Let $\{J_\lambda; 0 < \lambda < \infty\}$ be a pseudo-resolvent of linear contractions on $L_1(S, \Sigma, \mu; Y)$ such that, for some constant $K \geq 1$, $\sup_{\lambda > 0} \|\lambda J_\lambda f\|_\infty \leq K \|f\|_\infty$ for all $f \in L_1 \cap L_\infty$. Then for every $1 \leq p < \infty$ and every $f \in L_p$ the limits

$$\lim_{\lambda \rightarrow 0^+} \lambda(J_\lambda f)(s) \text{ and } \lim_{\lambda \rightarrow \infty} \lambda(J_\lambda f)(s)$$

exist almost everywhere on S .

Finally, the validity of the assertions in Theorems 2 and 3 about the Cesàro limits is guaranteed by the following theorem, which is contained as a special case in Theorems 18.2.1 and 18.3.3 (and a remark following it) of [6].

Theorem C. *Let g be a bounded and Lebesgue measurable Y -valued function on $(0, \infty)$. Then*

$$\lim_{t \rightarrow \infty} t^{-1} \int_0^t g(s) ds = \lim_{\lambda \rightarrow 0} \lambda \int_0^\infty e^{-\lambda t} g(t) dt$$

provided one of the limits exists. The same assertion still holds when " $t \rightarrow \infty$ " and " $\lambda \rightarrow 0^+$ " are replaced by " $t \rightarrow 0^+$ " and " $\lambda \rightarrow \infty$ ", respectively.

Remark. Since $L_p \cap L_\infty$ is dense in L_p , the conclusion (ii) of Theorems 2 and 3 might be extended to include all f in L_p provided that one could prove such a maximal ergodic inequality:

$$(*) \quad \mu(\{s; \sup_{t \geq 0} |t^{-1}(S(t)f)(s)| > a\}) \leq Ca^{-p} \|f\|_p^p \quad (a > 0, f \in L_p).$$

(cf. [4, Theorem 1.1]). A key to $(*)$ would be the following cosine version of Chacon maximal ergodic inequality:

$$(**) \quad \int_{e^*(ka)} (a - |f^{a-}(s)|) d\mu \leq \int_s |f^{a+}(s)| d\mu \quad (a > 0, f \in L_p),$$

where $e^*(ka) := \{s; \sup_{n \geq 1} \left| \frac{1}{n} \sum_{i=0}^{n-1} (C(i)f)(s) \right| > ka\}$, $f^{a-}(s) := \frac{f(s)}{|f(s)|} \min(a, |f(s)|)$ and $f^{a+}(s) := f(s) - f^{a-}(s)$.

if $(**)$ is true, then one can use the same arguments in Theorem 2 of [5] to derive a continuous version of $(**)$, from which then follows a dominated ergodic theorem (like Theorem 3 of [5]) and in particular $(*)$. Moreover, this would enable one to directly prove the completed Theorems 2 & 3, without using Theorems B and C. At present, the author has not found a proof of $(*)$ or $(**)$ yet.
